My questions: How can I implement this logic in my project? Is there a better way to do this than the way I currently do it? What is the best way to explore the large dataset and get to know the data? A: Note that I work for Qlik (makers of Q). Data discovery can be done using Qlik's data exploration capabilities. The way you did it was correct. You were also right that having a file with records with the same index number would help you. One thing to note is that in your code you are working with a file with multiple data in it. If you want to work with a single record, you need to extract out the data from a file with multiple records. Below is a link to a video tutorial by Q In your case, if you are looking for a particular column and want to know the values, you could simply use the extract function and add a new column on the left. Below is an example of a record with the same index. You would have multiple records in this file. Below is a link to the same documentation for data exploration Below is an example of the extract function with a specific column and display on a new column I hope that helps. Long-term efficacy of acellular dermal matrix allograft in the treatment of breast augmentation revision surgery. The purpose of this study was to determine the long-term efficacy of acellular dermal matrix (ADM) allograft in the treatment of breast augmentation revision surgery. Twenty-eight breast revision cases of patients undergoing bilateral 82157476af
